Maintenance Manual for Q-Drive

Chapter 1: Overview

The Q-Drive is a fictional propulsion system designed for deep space travel. It operates using zero-point energy extraction.

Chapter 2: Safety Protocols

Always wear thermal shielding when inspecting the core. The core temperature can reach up to 5000 Kelvin during normal operations.

In case of a containment breach, initiate Protocol Gamma. Protocol Gamma seals the engineering deck and vents the plasma manifold.

Chapter 3: Diagnostics

To run a full diagnostic, connect the terminal to the primary databus and execute the 'qd-diag --full' command.

Error code E-77 indicates a misalignment in the magnetic confinement field. If E-77 occurs, recalibrate the field coils before restarting the drive.

Chapter 4: Maintenance Schedule

The plasma injectors should be replaced every 50,000 light-years or 10 years, whichever comes first.

Coolant fluid must be flushed and replaced annually.
